

Module 5: Reviewing and Testing AI Code

From plausible output to verified behavior

Module 5: Reviewing and Testing AI Code

Primary sources: Osmani, Chapter 5; Thomas & Hunt, Topics 16-27 and Topic 42: Property-Based Testing.

Learning Outcomes

- Analyze AI-generated code for correctness and quality.
 - Identify common failure patterns.
 - Distinguish superficial correctness from true correctness.
 - Apply testing strategies to validate outputs.
-

Review, Refine, Own

Osmani's core message for generated code: understanding is not optional.

You own:

- What was generated.
 - What was accepted.
 - What was changed.
 - What was verified.
 - What risk remains.
-

Review Pipeline

Superficial Correctness

Code may appear correct because it:

- Matches naming conventions.
- Compiles.
- Handles the example input.
- Uses familiar libraries.
- Includes comments that sound confident.

None of these prove behavior.

Review Checklist

- Does it implement the stated requirement?
 - What assumptions did it add?
 - What edge cases are missing?
 - Is error handling intentional?
 - Is the design testable?
 - Does it expose secrets or unsafe behavior?
 - Are dependencies appropriate?
-

Majority Solution Problem

Osmani warns that AI often gives the common solution, not the appropriate solution.

Review for:

- Generic assumptions that do not match this project.
 - Algorithms that work for small cases but not real inputs.
 - Tutorial-style code, comments, or global state.
 - Library choices that add unnecessary dependency or risk.
 - Missing behavior where the prompt was ambiguous.
-

Tests as Design

Osmani emphasizes that tests turn generated code into code you can own.

For AI-assisted work:

- Ask for tests before accepting implementation.
 - Review tests as critically as code.
 - Avoid tests that merely mirror the implementation.
 - Add regression tests for AI mistakes.
-

Tools Make Review Real

From The Basic Tools, reviewing AI code is practical tool work.

- Plain text makes prompts, diffs, and logs inspectable.
 - Version control isolates AI changes for review and rollback.
 - Debuggers and shell commands reveal actual behavior.
 - Text manipulation helps compare outputs and find repeated patterns.
 - Daybooks preserve what you tried, rejected, and learned.
-

Pragmatic Paranoia for AI Code

Chapter 4 reinforces a defensive review stance.

- Design by contract: check preconditions, postconditions, and invariants.
 - Crash early: prefer visible failures over hidden corruption.
 - Assertions: expose impossible states during development.
 - Resource balance: verify cleanup, ownership, and lifecycle behavior.
 - Small steps: review one coherent change before asking for the next.
-

Test Pyramid for AI Code

- Unit tests: fast checks of isolated behavior.
- Integration tests: verify components work together.
- End-to-end tests: validate user-visible workflow.

Safety and security checks are cross-cutting: verify refusal, bounds, permissions, and secrets handling at every relevant level.

Property Thinking

Property-based testing asks what must always be true.

Examples for Java command parsing:

- Parsing then serializing preserves arguments.
 - Invalid commands never execute tools.
 - Sandbox paths never escape the workspace.
 - Empty input always fails safely.
-

Lab 3 Development Connection

As Lab 3 begins, implementation must remain inspectable.

Good evidence includes:

- Tool contracts.
 - Sandbox restrictions.
 - Tests proving restrictions.
 - Sample runs.
 - Copilot decisions and corrections.
-

Practice Activity

Give Copilot an intentionally incomplete implementation and ask it to review.

Then do a human review and compare:

- What did Copilot catch?
 - What did it miss?
 - Which issues require domain judgment?
-

Takeaways

- AI-generated code needs adversarial review.
- Tests are engineering evidence.
- Owning code means understanding failure behavior.
